So, buckle up, and let's embark on this journey into the fascinating world of multivariable calculus!

What Exactly Are Partial Derivatives?

Imagine a function that depends not on one, but on several variables. Think of the temperature on a hot day, which might depend on the time of day, your location (latitude and longitude), and even humidity. If you want to know how the temperature changes *specifically* with respect to time, while keeping all other factors constant, you're essentially asking for a partial derivative. In essence, a partial derivative measures the rate of change of a multivariable function with respect to *one* of its independent variables, while treating all other independent variables as constants. This is the key distinction from ordinary derivatives, which deal with functions of a single variable. Let's say we have a function $f(x, y)$. The partial derivative of f with respect

to x , denoted as $\frac{\partial f}{\partial x}$ or f_x , tells us how f changes as x changes, assuming y remains fixed. Similarly, the partial derivative of f with respect to y , denoted as $\frac{\partial f}{\partial y}$ or f_y , tells us how f changes as y changes, assuming x remains fixed.

Why Are Partial Derivatives So Important? (The "So What?" Factor)

The utility of partial derivatives extends far beyond theoretical mathematics. They are indispensable in numerous scientific and engineering disciplines:

1. **Physics:** Understanding wave propagation, heat transfer, fluid dynamics, and electromagnetism heavily relies on partial differential equations (PDEs), which are built upon partial derivatives. For instance, the heat equation describes how temperature distributes over time and space.
2. **Economics:** Analyzing how changes in factors like price, demand, and supply affect a company's profit or revenue involves partial derivatives. Marginal cost and marginal revenue are prime examples.
3. **Engineering:** Designing structures, optimizing manufacturing processes, and analyzing control systems all utilize partial derivatives. Stress and strain analysis in mechanical engineering, for example, often involves multivariable functions.
4. **Computer Graphics and Machine Learning:** Optimizing complex models, training neural networks, and rendering realistic images often involve calculating gradients, which are vectors of partial derivatives.
5. **Environmental Science:** Modeling pollution dispersion, weather patterns, and climate change involves complex multivariable functions and their rates of change.

In short, whenever you're dealing with a phenomenon influenced by multiple factors, and you need to understand the impact of changing just one of those factors, partial derivatives are your go-to tool.

Calculating Partial Derivatives: The Nuts and Bolts

The process of calculating partial derivatives is quite straightforward once you grasp the core concept of holding other variables constant. Let's illustrate with examples. Consider the function $f(x, y) = x^2y + 3x + y^3$.

Partial Derivative with Respect to x (f_x)

To find $\frac{\partial f}{\partial x}$, we treat y as a constant. Think of y as just a number.

1. The term x^2y : When differentiating with respect to x , y is a constant multiplier. The derivative of x^2 is $2x$. So, the derivative of x^2y is $2xy$.
2. The term $3x$: The derivative of $3x$ with respect to x is 3 .
3. The term y^3 : Since y is treated as a constant, y^3 is also a constant. The derivative of any constant is 0 .

Therefore, $\frac{\partial f}{\partial x} = 2xy + 3 + 0 = 2xy + 3$.

Partial Derivative with Respect to y (f_y)

To find $\frac{\partial f}{\partial y}$, we treat x as a constant. Think of x as just a number.

1. The term x^2y : When differentiating with respect to y , x^2 is a constant multiplier. The derivative of y is 1 . So, the derivative of x^2y is $x^2 \cdot 1 = x^2$.
2. The term $3x$: Since x is treated as a constant, $3x$ is also a constant. The derivative of a constant is 0 .
3. The term y^3 : The derivative of y^3 with respect to y is $3y^2$.

Therefore, $\frac{\partial f}{\partial y} = x^2 + 0 + 3y^2 = x^2 + 3y^2$.

Higher-Order Partial Derivatives

Just as we can take second, third, and higher-order derivatives in single-variable calculus, we can do the same with partial derivatives. These are called higher-order partial derivatives. For our function $f(x, y) = x^2y + 3x + y^3$, we've already found: $f_x = 2xy + 3$ $f_y = x^2 + 3y^2$ Now, let's find the second-order partial derivatives:

The Mixed Partial Derivatives (f_{xy} and f_{yx})

These are particularly interesting. f_{xy} means taking the partial derivative with respect to y *after* taking the partial derivative with respect to x . $f_{xy} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial y} (2xy + 3)$ Treating x as a constant: $\frac{\partial}{\partial y} (2xy) = 2x \cdot 1 = 2x$ $\frac{\partial}{\partial y} (3) = 0$ So, $f_{xy} = 2x$. Now, let's find f_{yx} , which means taking the partial derivative with respect to x *after* taking the partial derivative with respect to y . $f_{yx} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = \frac{\partial}{\partial x} (x^2 + 3y^2)$ Treating y as a constant: $\frac{\partial}{\partial x} (x^2) = 2x$ $\frac{\partial}{\partial x} (3y^2) = 0$ (since $3y^2$ is a constant with respect to x) So, $f_{yx} = 2x$. Notice that in this case, $f_{xy} = f_{yx}$. This is a common occurrence and is related to Clairaut's Theorem (also known as Schwarz's Theorem), which states that if the second-order partial derivatives are continuous in a region, then the mixed partial derivatives are equal in that region. This is a very useful property!

The Pure Second-Order Partial Derivatives (f_{xx} and f_{yy})

$f_{xx} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial x} (2xy + 3)$ Treating y as a constant: $\frac{\partial}{\partial x} (2xy) = 2y \cdot 1 = 2y$ $\frac{\partial}{\partial x} (3) = 0$ So, $f_{xx} = 2y$. $f_{yy} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) = \frac{\partial}{\partial y} (x^2 + 3y^2)$ Treating x as a constant: $\frac{\partial}{\partial y} (x^2) = 0$ $\frac{\partial}{\partial y} (3y^2) = 3 \cdot 2y = 6y$ So, $f_{yy} = 6y$.

Putting Your Knowledge to the Test: Multiple Choice Questions on Partial Derivatives

Now that we've covered the fundamentals, let's test your understanding with some multiple choice questions. These questions are designed to assess your ability to apply the rules of partial differentiation and recognize common scenarios.

Question 1

If $f(x, y) = 5x^3y^2 - 2xy + 7y$, what is $\frac{\partial f}{\partial x}$? a) $15x^2y^2 - 2y$ b) $15x^2y^2 - 2x$ c) $5x^3y^2 - 2y$ d) $15x^2y^2 - 2y + 7$ **Solution:** To find $\frac{\partial f}{\partial x}$, treat y as a constant. The derivative of $5x^3y^2$ with respect to x is $5(3x^2)y^2 = 15x^2y^2$. The derivative of $-2xy$ with respect to x is $-2y$. The derivative of $7y$ with respect to x is 0 (since $7y$ is treated as a constant). Therefore, $\frac{\partial f}{\partial x} = 15x^2y^2 - 2y$. **Correct Answer:** a)

Question 2

For the function $g(x, y) = e^{x^2y} + \sin(x+y)$, what is $\frac{\partial g}{\partial y}$? a) $xe^{x^2y} + \cos(x+y)$ b) $2xy e^{x^2y} + \cos(x+y)$ c) $2x e^{x^2y} + \cos(x+y)$ d) $x^2 e^{x^2y} + \cos(x+y)$ **Solution:** To find $\frac{\partial g}{\partial y}$, treat x as a constant. For the term e^{x^2y} , we use the chain rule. The derivative of e^u is $e^u \frac{du}{dy}$. Here, $u = x^2y$. So, $\frac{du}{dy} = x^2$. Thus, the derivative of e^{x^2y} with respect to y is $e^{x^2y} \cdot x^2$. For the term $\sin(x+y)$, the derivative with respect to y is $\cos(x+y) \cdot \frac{d}{dy}(x+y) = \cos(x+y) \cdot 1 = \cos(x+y)$. Therefore, $\frac{\partial g}{\partial y} = x^2 e^{x^2y} + \cos(x+y)$. **Correct Answer:** d)

Question 3

Given $h(x, y, z) = \frac{x}{y} + \frac{y}{z} + \frac{z}{x}$, what is $\frac{\partial h}{\partial z}$? a) $-\frac{y}{z^2} - \frac{z}{x^2}$ b) $\frac{y}{z^2} + \frac{1}{x}$ c) $\frac{y}{z^2} - \frac{z}{x^2}$ d) $-\frac{y}{z^2} + \frac{1}{x}$ **Solution:** To find $\frac{\partial h}{\partial z}$, treat x and y as constants. The derivative of $\frac{x}{y}$ with respect to z is 0 . The derivative of $\frac{y}{z}$ with respect to z is $y \cdot \frac{d}{dz}(z^{-1}) = y \cdot (-1)z^{-2} = -\frac{y}{z^2}$. The derivative of $\frac{z}{x}$ with respect to z is $\frac{1}{x} \cdot \frac{d}{dz}(z) = \frac{1}{x} \cdot 1 = \frac{1}{x}$. Therefore, $\frac{\partial h}{\partial z} = 0 - \frac{y}{z^2} + \frac{1}{x} = \frac{1}{x} - \frac{y}{z^2}$. **Correct Answer:** d)

Question 4

Consider the function $f(x, y) = x^4 - 3x^2y^3 + 2y$. What is the second-order partial derivative f_{yy} ? a) $-18xy^2$ b) $-18x^2y$ c) $-18xy$ d) $-6y$ **Solution:** First, find f_y : $f_y = \frac{\partial}{\partial y}(x^4 - 3x^2y^3 + 2y)$ Treat x as a constant. $f_y = 0 - 3x^2(3y^2) + 2 = -9x^2y^2 + 2$. Now, find $f_{yy} = \frac{\partial}{\partial y}(f_y)$: $f_{yy} = \frac{\partial}{\partial y}(-9x^2y^2 + 2)$ Treat x as a constant. $f_{yy} =$

$-9x^2(2y) + 0 = -18x^2y$. **Correct Answer:** b)

Question 5

If $f(x, y) = \ln(x^2 + y^2)$, what is f_{xy} ? a) $\frac{2x(y^2 - x^2)}{(x^2 + y^2)^2}$ b) $\frac{2y(x^2 - y^2)}{(x^2 + y^2)^2}$ c) $\frac{2x}{(x^2 + y^2)}$ d) $\frac{2y}{(x^2 + y^2)}$ **Solution:** First, find f_x : $f_x = \frac{\partial}{\partial x} (\ln(x^2 + y^2))$ Using the chain rule, $\frac{d}{du}(\ln u) = \frac{1}{u}$. Here $u = x^2 + y^2$. $\frac{\partial u}{\partial x} = 2x$. So, $f_x = \frac{1}{x^2 + y^2} \cdot (2x) = \frac{2x}{x^2 + y^2}$. Now, find $f_{xy} = \frac{\partial}{\partial y} (f_x) = \frac{\partial}{\partial y} \left(\frac{2x}{x^2 + y^2} \right)$. We use the quotient rule: $\left(\frac{u}{v} \right)' = \frac{u'v - uv'}{v^2}$. Let $u = 2x$ and $v = x^2 + y^2$. When differentiating with respect to y , $u' = \frac{\partial}{\partial y} (2x) = 0$. $v' = \frac{\partial}{\partial y} (x^2 + y^2) = 2y$. So, $f_{xy} = \frac{(0)(x^2 + y^2) - (2x)(2y)}{(x^2 + y^2)^2} = \frac{-4xy}{(x^2 + y^2)^2}$. Wait, let me re-check the question and my steps... Ah, I see a potential for error in my manual calculation for the provided options. Let's re-evaluate the options and my calculation carefully. Let's re-calculate f_x and then f_{xy} to be absolutely sure. $f_x = \frac{2x}{x^2 + y^2}$. Now $f_{xy} = \frac{\partial}{\partial y} \left(\frac{2x}{x^2 + y^2} \right)$. Using quotient rule again, with $u=2x$ and $v=x^2+y^2$. $u' = \frac{\partial u}{\partial y} = 0$ $v' = \frac{\partial v}{\partial y} = 2y$ $f_{xy} = \frac{(0)(x^2+y^2) - (2x)(2y)}{(x^2+y^2)^2} = \frac{-4xy}{(x^2+y^2)^2}$. It seems none of the provided options exactly match my calculation. Let me double-check common mistakes. Is it possible the question or options have a typo? Or have I made a consistent error? Let's try calculating f_y and then f_{yx} to see if we get the same result (due to Clairaut's Theorem). $f_y = \frac{\partial}{\partial y} (\ln(x^2 + y^2)) = \frac{1}{x^2 + y^2} \cdot (2y) = \frac{2y}{x^2 + y^2}$. Now $f_{yx} = \frac{\partial}{\partial x} \left(\frac{2y}{x^2 + y^2} \right)$. Let $u = 2y$ and $v = x^2 + y^2$. $u' = \frac{\partial u}{\partial x} = 0$. $v' = \frac{\partial v}{\partial x} = 2x$. $f_{yx} = \frac{(0)(x^2+y^2) - (2y)(2x)}{(x^2+y^2)^2} = \frac{-4xy}{(x^2+y^2)^2}$. My calculations consistently yield $\frac{-4xy}{(x^2 + y^2)^2}$. It's possible there's a typo in the provided options. However, if we were forced to choose the *closest* or if there was a sign error in the options, option (a) has a $2x$ in the numerator and option (b) has a $2y$, but the denominator seems to be squared correctly. Let's assume for a moment that the question intended something slightly different or there was a transcription error. Let me consider if I made a mistake in the chain rule application. $f(x,y) = \ln(u)$, where $u = x^2 + y^2$. $\frac{\partial f}{\partial x} = \frac{1}{u} \frac{\partial u}{\partial x} = \frac{1}{x^2 + y^2} (2x) = \frac{2x}{x^2 + y^2}$. This is correct. $\frac{\partial f}{\partial y} = \frac{1}{u} \frac{\partial u}{\partial y} = \frac{1}{x^2 + y^2} (2y) = \frac{2y}{x^2 + y^2}$. This is correct. Now, $f_{xy} = \frac{\partial}{\partial y} \left(\frac{2x}{x^2 + y^2} \right)$. This is $\frac{d}{dy} \left(\frac{2x}{x^2 + y^2} \right)$. The derivative of the numerator $2x$ with respect to y is 0 . The derivative of the denominator $x^2 + y^2$ with respect to y is $2y$. Using the quotient rule: $\frac{(0)(x^2 + y^2) - (2x)(2y)}{(x^2 + y^2)^2} = \frac{-4xy}{(x^2 + y^2)^2}$. Given the discrepancy, I cannot confidently select one of the provided options. It is highly probable that there is an error in the question's options. If forced to guess a common mistake pattern, sometimes the derivative of

the numerator might be incorrectly applied or a sign error. Let's re-examine the structure of the options: a) $\frac{2x(y^2 - x^2)}{(x^2 + y^2)^2}$ b) $\frac{2y(x^2 - y^2)}{(x^2 + y^2)^2}$ These options look like they might result from a slightly different function or a different differentiation path. Let's assume, hypothetically, that the function was different. For example, if the function was $f(x,y) = \frac{x}{x^2+y^2}$ or similar. However, sticking to the given function $f(x, y) = \ln(x^2 + y^2)$, my calculation of $f_{xy} = \frac{-4xy}{(x^2 + y^2)^2}$ is robust. Without further clarification or correction of the options, I cannot provide a definitive answer from the choices given. **(Self-correction/clarification):** Upon re-reading and re-calculating carefully, and considering common errors, I suspect there might be a misunderstanding or typo in my interpretation of the *options themselves* rather than the calculation. Let's assume the calculation is correct and see if any option can be *derived* from it, or if there's a very common pitfall. Revisiting $f_x = \frac{2x}{x^2+y^2}$. $f_{xy} = \frac{\partial}{\partial y} \left(\frac{2x}{x^2+y^2} \right)$. This is the derivative of $2x \cdot (x^2+y^2)^{-1}$ with respect to y . Using the product rule: $\frac{d}{dy}(uv) = u'v + uv'$. Here, $u=2x$ (constant w.r.t y), $v=(x^2+y^2)^{-1}$. $u' = \frac{\partial}{\partial y}(2x) = 0$. $v' = \frac{\partial}{\partial y}((x^2+y^2)^{-1}) = -1(x^2+y^2)^{-2} \cdot (2y) = \frac{-2y}{(x^2+y^2)^2}$. So, $f_{xy} = (0)(x^2+y^2)^{-1} + (2x) \left(\frac{-2y}{(x^2+y^2)^2} \right) = \frac{-4xy}{(x^2+y^2)^2}$. My calculation remains consistent. It's possible the options are designed to catch a specific type of error, or there's a typo. Let's look at option (a) again: $\frac{2x(y^2 - x^2)}{(x^2 + y^2)^2}$. If the numerator was $-4xy$, it would be correct. This structure suggests a mistake in the differentiation of the numerator or denominator in a way that leads to x^2 or y^2 terms in the numerator. Given the problem as stated, and my rigorous calculation, I cannot confidently select an answer from the provided options. This often happens in test scenarios – it's important to trust your calculations and if there's a strong discrepancy, to note it. However, in the context of a multiple-choice question and assuming there *is* a correct answer among them, let me consider a very common error pattern. Sometimes, in the quotient rule application for $f_{xy} = \frac{\partial}{\partial y} \left(\frac{2x}{x^2+y^2} \right)$, the derivative of the numerator is mistakenly taken with respect to y , or the product rule is misapplied. If, hypothetically, the numerator was meant to involve y , or the differentiation w.r.t y was applied to the $2x$ incorrectly, that might lead to a y^2 or x^2 in the numerator. Let me assume there's a typo in the options and proceed with a pedagogical approach: The process to arrive at the correct answer involves correctly applying the chain rule and quotient rule for partial derivatives. **Final Decision on Question 5:** Due to the discrepancy between my verified calculation and the provided options, I must state that none of the options appear to be correct for the function $f(x, y) = \ln(x^2 + y^2)$. The correct answer for f_{xy} is $\frac{-4xy}{(x^2 + y^2)^2}$. If this were a real exam, I would flag this question.

Question 6 (Bonus Conceptual Question)

If $f(x,y)$ is a differentiable function, and $\frac{\partial f}{\partial x} = 0$ for all x and y , what can we conclude about $f(x,y)$? a) $f(x,y)$ is a constant function with respect to x only. b) $f(x,y)$ is a constant function with respect to y only. c) $f(x,y)$ is a constant function. d) $f(x,y)$ is identically zero. **Solution:** If $\frac{\partial f}{\partial x} = 0$ for all x and y , it means that $f(x,y)$ does not change as x changes, regardless of the value of y . This

implies that $f(x,y)$ must be a function of y only, i.e., $f(x,y) = g(y)$ for some function g . However, the question asks what we can conclude about $f(x,y)$ being a constant function. If $\frac{\partial f}{\partial x} = 0$ for all x, y , then $f(x,y)$ is indeed a constant with respect to x . But if $f(x,y) = g(y)$, then $g(y)$ could still vary with y . Therefore, $f(x,y)$ is not necessarily a constant function overall. However, it *is* a constant with respect to x . Let's re-read the question: "what can we conclude about $f(x,y)$?". If $\frac{\partial f}{\partial x} = 0$ for all x and y , then $f(x,y)$ is a function of y alone. Let $f(x,y) = g(y)$. The partial derivative of $g(y)$ with respect to x is 0 . The partial derivative of $g(y)$ with respect to y is $g'(y)$. So $f(x,y)$ is a function that doesn't depend on x . Consider $f(x,y) = 5y^2$. Then $\frac{\partial f}{\partial x} = 0$. This is not a constant function overall. Consider $f(x,y) = 5$. Then $\frac{\partial f}{\partial x} = 0$. This is a constant function. Consider $f(x,y) = 0$. Then $\frac{\partial f}{\partial x} = 0$. This is identically zero. The statement " $\frac{\partial f}{\partial x} = 0$ for all x and y " means that $f(x,y)$ is independent of x . So $f(x,y)$ can be written as $g(y)$. If $g(y)$ is itself a constant, then $f(x,y)$ is a constant. If $g(y)$ is not a constant, then $f(x,y)$ is not a constant. Let's look closely at the options again: a) $f(x,y)$ is a constant function with respect to x only. This is true, as $\frac{\partial f}{\partial x} = 0$. b) $f(x,y)$ is a constant function with respect to y only. This is not necessarily true. c) $f(x,y)$ is a constant function. This is not necessarily true. d) $f(x,y)$ is identically zero. This is not necessarily true. The most accurate conclusion is that $f(x,y)$ does not change with respect to x . Therefore, it is constant with respect to x . Option (a) best captures this. **Correct Answer: a)**

Mastering Multiple Choice Questions on Partial

Derivatives

Partial derivatives are a cornerstone of multivariable calculus, essential for understanding how functions change with respect to individual variables when multiple variables are involved. In academic settings, particularly in advanced high school mathematics, undergraduate calculus courses, and various STEM disciplines, the ability to correctly solve problems involving partial derivatives is often assessed through multiple-choice questions (MCQs). These questions, while seemingly straightforward, can be deceptive, requiring a deep conceptual understanding rather than just rote memorization. This article delves into the nuances of tackling multiple-choice questions on partial derivatives, offering analytical strategies, common pitfalls to avoid, and an exploration of key concepts and their applications, all designed to help students achieve mastery and excel in their assessments.

Understanding the Core Concept of Partial Differentiation

Before diving into MCQs, it's crucial to solidify the fundamental understanding of partial derivatives. Unlike ordinary derivatives, which measure the rate of change of a function with respect to a single independent variable, partial derivatives measure the rate of change of a multivariable function with respect to one specific variable, while treating all other independent variables as constants. For a function $f(x, y)$, the partial derivative with respect to x , denoted as $\frac{\partial f}{\partial x}$ or $f_x(x, y)$, is found by differentiating f with respect to x and holding y constant. Similarly, $\frac{\partial f}{\partial y}$ or $f_y(x, y)$ is found by differentiating f with respect to y while holding x constant.

This concept extends to functions with more than two variables, such as $f(x, y, z)$. We can find $\frac{\partial f}{\partial x}$, $\frac{\partial f}{\partial y}$, and $\frac{\partial f}{\partial z}$ by applying the same principle – differentiate with respect to the chosen variable and treat the others as constants.

Common Structures of Partial Derivative MCQs

Multiple-choice questions on partial derivatives typically fall into several categories:

Direct Computation of First-Order Partial Derivatives

These are the most basic MCQs. They present a function of two or more variables and ask for one or more of its first-order partial derivatives. For example:

Question: If $f(x, y) = x^3y^2 - 5x + 2y^4$, what is $\frac{\partial f}{\partial x}$?

Options: (a) $3x^2y^2 - 5$ (b) $x^3y^2 - 5x$ (c) $3x^2y^2 - 5 + 8y^3$ (d) $x^3y^2 - 5 + 2y^4$

Analysis: To solve this, we treat y as a constant. Differentiating x^3y^2 with respect to x gives $3x^2y^2$. Differentiating $-5x$ with respect to x gives -5 . Differentiating $2y^4$ (a constant with respect to x) gives 0 . Therefore, $\frac{\partial f}{\partial x} = 3x^2y^2 - 5$. Option (a) is the correct answer.

Second-Order Partial Derivatives (Mixed and Unmixed)

These questions involve finding second-order partial derivatives. There are two types: unmixed (e.g., $\frac{\partial^2 f}{\partial x^2}$) and mixed (e.g., $\frac{\partial^2 f}{\partial x \partial y}$). A crucial theorem here is Clairaut's Theorem (also known as Schwarz's Theorem), which states that if the second partial derivatives of a function are continuous in a region, then the mixed partial derivatives are equal, i.e., $\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial^2 f}{\partial y \partial x}$.

Question: For $f(x, y) = e^{xy} \sin(x)$, find $\frac{\partial^2 f}{\partial y \partial x}$.

Analysis: First, find $\frac{\partial f}{\partial x}$. Using the product rule: $\frac{\partial f}{\partial x} = (y e^{xy}) \sin(x) + e^{xy} \cos(x)$. Now, find $\frac{\partial^2 f}{\partial y \partial x}$ by differentiating $\frac{\partial f}{\partial x}$ with respect to y , treating x as a constant. The term $(y e^{xy}) \sin(x)$ differentiates to $(1 \cdot e^{xy} + y \cdot x e^{xy}) \sin(x) = (e^{xy} + xy e^{xy}) \sin(x)$. The term $e^{xy} \cos(x)$ is a constant with respect to y , so its derivative is 0. Thus, $\frac{\partial^2 f}{\partial y \partial x} = (e^{xy} + xy e^{xy}) \sin(x)$.

Alternatively, one could calculate $\frac{\partial f}{\partial y}$ first: $\frac{\partial f}{\partial y} = x e^{xy} \sin(x)$. Then differentiate with respect to x : $\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x} (x e^{xy} \sin(x))$. Using the product rule: $(1 \cdot e^{xy} + x \cdot x e^{xy}) \sin(x) + x e^{xy} \cos(x) = (e^{xy} + x^2 e^{xy}) \sin(x) + x e^{xy} \cos(x)$.

Note: The previous example calculation for $\frac{\partial^2 f}{\partial y \partial x}$ was incomplete. Let's redo it correctly. $\frac{\partial f}{\partial x} = y e^{xy} \sin(x) + e^{xy} \cos(x)$. Now, differentiate with respect to y : $\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y} (y e^{xy} \sin(x) + e^{xy} \cos(x)) = (1 \cdot e^{xy} + y \cdot x e^{xy}) \sin(x) + (x e^{xy}) \cos(x) = (e^{xy} + xy e^{xy}) \sin(x) + x e^{xy} \cos(x)$.

Chain Rule for Partial Derivatives

When the variables of a function depend on other variables, the chain rule becomes essential. For a function $z = f(x, y)$, where $x = g(t)$ and $y = h(t)$, the derivative of z with respect to t is $\frac{dz}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt}$. For more complex dependencies, like $z = f(x, y)$ with $x = g(u, v)$ and $y = h(u, v)$, we have:

$$\frac{\partial z}{\partial u} = \frac{\partial f}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial u}$$

$$\frac{\partial z}{\partial v} = \frac{\partial f}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial v}$$

Question: Let $z = x^2 + y^2$, where $x = t \cos(t)$ and $y = t \sin(t)$. Find $\frac{dz}{dt}$.

Options: (a) $2t^3$ (b) $2t^2 + t$ (c) $2t$ (d) $2t^3 - t$

Analysis: First, find the partial derivatives of z with respect to x and y : $\frac{\partial z}{\partial x} = 2x$ and $\frac{\partial z}{\partial y} = 2y$. Next, find the ordinary derivatives of x and y with respect to t using the product rule:

$$\frac{dx}{dt} = 1 \cdot \cos(t) + t(-\sin(t)) = \cos(t) - t\sin(t)$$

$$\frac{dy}{dt} = 1 \cdot \sin(t) + t(\cos(t)) = \sin(t) + t\cos(t)$$

Now, apply the chain rule: $\frac{dz}{dt} = \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt}$

$$\frac{dz}{dt} = (2x)(\cos(t) - t\sin(t)) + (2y)(\sin(t) + t\cos(t))$$

Substitute $x = t \cos(t)$ and $y = t \sin(t)$:

$$\frac{dz}{dt} = 2(t \cos(t))(\cos(t) - t\sin(t)) + 2(t \sin(t))(\sin(t) + t\cos(t))$$

$$= 2t \cos^2(t) - 2t^2 \cos(t)\sin(t) + 2t \sin^2(t) + 2t^2 \sin(t)\cos(t)$$

The terms $-2t^2 \cos(t)\sin(t)$ and $+2t^2 \sin(t)\cos(t)$ cancel out.

$$= 2t \cos^2(t) + 2t \sin^2(t)$$

$$= 2t (\cos^2(t) + \sin^2(t))$$

Using the identity $\cos^2(t) + \sin^2(t) = 1$:

$$= 2t(1) = 2t. \text{ The correct answer is (c).}$$

Gradient Vector and Directional Derivatives

The gradient of a function $f(x, y)$ is a vector $\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle$. It points in the direction of the greatest rate of increase of the function. The directional derivative of f in the direction of a unit vector $\mathbf{u}$ is given by $D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u}$. These concepts are often tested in MCQs.

Question: Find the gradient of $f(x, y) = x^2y - \sin(y)$ at the point $(1, \pi/2)$.

Options: (a) $\langle \pi, 1 \rangle$ (b) $\langle \pi, 0 \rangle$ (c) $\langle \pi^2/4, 1 \rangle$ (d) $\langle \pi^2/4, 0 \rangle$

Analysis: Calculate the partial derivatives: $\frac{\partial f}{\partial x} = 2xy$ and $\frac{\partial f}{\partial y} = x^2 - \cos(y)$. Evaluate these at the point $(1, \pi/2)$:

$$\frac{\partial f}{\partial x}(1, \pi/2) = 2(1)(\pi/2) = \pi$$

$$\frac{\partial f}{\partial y}(1, \pi/2) = 1^2 - \cos(\pi/2) = 1 - 0 = 1$$

So, $\nabla f(1, \pi/2) = \langle \pi, 1 \rangle$. The correct answer is (a).

Applications: Optimization and Related Rates

Partial derivatives are fundamental to optimization problems in multivariable calculus (finding maxima and minima using critical points where $\nabla f = \mathbf{0}$ or partial derivatives

are undefined) and related rates problems. MCQs might pose scenarios where one needs to set up or interpret the partial derivative expressions.

Strategies for Tackling Partial Derivative MCQs

Read the Question Carefully

This is paramount for any MCQ. Pay close attention to what is being asked: first-order, second-order, mixed derivatives, specific variables to differentiate with respect to, or a specific point for evaluation. Misinterpreting "partial derivative with respect to x " as "derivative with respect to x " (if there were only one variable) is a common mistake. Also, distinguish between ordinary and partial derivatives in the context of the problem.

Identify the Constants

When finding $\frac{\partial f}{\partial x}$, remember that y (and any other independent variables not being differentiated with respect to) is treated as a constant. This means terms that are purely functions of these other variables (like $2y^4$ in our first example) will differentiate to zero. Conversely, when finding $\frac{\partial f}{\partial y}$, x is the constant.

Apply Differentiation Rules Methodically

Ensure a firm grasp of basic differentiation rules: power rule, product rule, quotient rule, chain rule, and derivatives of trigonometric, exponential, and logarithmic functions. Apply them systematically when differentiating with respect to the designated variable. For functions of multiple variables, it's often helpful to write down the derivatives of individual components explicitly.

Watch Out for Common Pitfalls

Confusing Variables: Forgetting which variable is being held constant is a frequent error.

Incorrect Application of Rules: Errors in applying the product rule or chain rule, especially in complex functions, are common.

Algebraic Simplification Errors: Mistakes in simplifying the final expression can lead to choosing an incorrect option.

Ignoring the Point of Evaluation: For questions requiring evaluation at a specific point, make sure to substitute the correct values for the variables after computing the derivative.

Misunderstanding Notation: Familiarize yourself with different notations for partial derivatives (f_x , $\frac{\partial f}{\partial x}$, f_{xx} , $\frac{\partial^2 f}{\partial x^2}$).

Misinterpreting Chain Rule Scenarios: Ensure you correctly identify how the variables of the outer function depend on the variables of the inner functions.

Use the Options as a Guide (Strategic Guessing)

If you're stuck, look at the provided options. Can you eliminate any options based on a quick check of the function's structure? For example, if a function contains x^3 and you're differentiating with respect to x , you expect a term with x^2 . If an option lacks this, it might be incorrect. For chain rule problems, the structure of the derivatives of the intermediate variables can give clues.

Practice with a Variety of Problems

The best way to excel is through consistent practice. Work through numerous examples from textbooks, online resources, and past exams. Focus on understanding *why* a particular method works and *where* errors can occur.

Leveraging LSI Keywords in Practice

As you practice, consciously think about related terms: **multivariable calculus, calculus III, differentiation, rate of change, tangent plane, optimization, directional derivative, gradient vector, implicit differentiation, related rates, chain rule applications.**

Understanding how these concepts interrelate will deepen your comprehension and ability to solve diverse problems, including those presented in MCQ format.

Advanced Topics and Their MCQ Manifestations

Beyond basic computation, MCQs can probe deeper understanding:

Implicit Differentiation Involving Partial Derivatives

When an equation defines one variable implicitly as a function of others, partial derivatives can be used. For $F(x, y, z) = 0$, if z is a function of x and y , then $\frac{\partial z}{\partial x} = -\frac{\partial F / \partial x}{\partial F / \partial z}$ and $\frac{\partial z}{\partial y} = -\frac{\partial F / \partial y}{\partial F / \partial z}$. MCQs might require applying this formula.

Partial Differential Equations (PDEs)

While a full PDE course is extensive, introductory MCQs might ask if a given function is a solution to a simple PDE. For instance, checking if $u(x, t) = e^{-kt} \sin(x)$ satisfies the heat equation $\frac{\partial u}{\partial t} = k \frac{\partial^2 u}{\partial x^2}$. This involves computing the required partial derivatives and substituting them into the equation.

Taylor Series for Multivariable Functions

The second-order Taylor expansion of $f(x, y)$ around (a, b) involves second-order partial derivatives: $f(x, y) \approx f(a, b) + f_x(a, b)(x-a) + f_y(a, b)(y-b) + \frac{1}{2!} [f_{xx}(a, b)(x-a)^2 + 2f_{xy}(a, b)(x-a)(y-b) + f_{yy}(a, b)(y-b)^2]$. MCQs might ask to compute the coefficients of such an expansion or verify the formula itself.

Questions & Answers About multiple choice questions on partial derivatives

No	Question	Answer
1	What's the core concept behind finding a partial derivative of a multivariable function?	It's about isolating the effect of changing *one* variable while holding all others constant. You treat the other variables as if they were just numbers.

2	If I have a function $f(x, y)$, what does $\partial f/\partial x$ represent geometrically?	It represents the slope of the tangent line to the surface $z = f(x, y)$ in the direction parallel to the x-axis. Essentially, how the function's value changes as you move only in the x-direction.
3	When calculating $\partial f/\partial y$ for $f(x, y, z)$, what do I do with x and z?	You treat them as constants. This means their derivatives with respect to y are zero. You only focus on the terms containing y.
4	What's the difference between a first-order and a second-order partial derivative?	A first-order partial derivative, like $\partial f/\partial x$, is the derivative of the original function with respect to one variable. A second-order partial derivative, like $\partial^2 f/\partial x^2$ or $\partial^2 f/\partial y \partial x$, is the derivative of a first-order partial derivative.
5	What are 'mixed partial derivatives' and why are they important?	Mixed partial derivatives involve taking partial derivatives with respect to different variables, like $\partial^2 f/\partial y \partial x$. They are important because of Clairaut's Theorem (or Schwarz's Theorem), which states that under certain continuity conditions, the order of differentiation doesn't matter ($\partial^2 f/\partial y \partial x = \partial^2 f/\partial x \partial y$).
6	How do partial derivatives relate to the gradient vector?	The gradient of a function $F(x, y, z)$, denoted ∇F , is a vector whose components are the first-order partial derivatives of F with respect to each variable: $\nabla F = \langle \partial F/\partial x, \partial F/\partial y, \partial F/\partial z \rangle$. It points in the direction of the greatest rate of increase of the function.
7	What kind of problems typically involve partial derivatives?	Problems involving rates of change in multiple dimensions, optimization (finding maxima/minima), related rates, physics (wave equations, heat diffusion), economics (utility functions), and many more scientific and engineering fields.
8	If a function's partial derivatives are all zero at a point, does that automatically mean it's a maximum or minimum?	Not necessarily. A point where all first-order partial derivatives are zero is called a critical point. It could be a local maximum, a local minimum, or a saddle point. You need to use the Second Derivative Test to classify it.
