Linear programming is a powerful mathematical technique used to optimize a particular objective function, subject to a set of constraints. It finds wide applications in various fields, including business, engineering, and economics. This will explore the fundamentals of linear programming, delve into solved examples, and demonstrate its practical applications.

What is Linear Programming?

Linear programming is a mathematical method for determining the best possible outcome (maximum profit or minimum cost) in a given situation with limited resources. It involves formulating a linear objective function, which represents the quantity to be optimized, and a set of linear constraints, which represent the limitations or restrictions on the decision variables. **Key Elements of Linear Programming:**

- **Decision Variables:** These are the unknown quantities that need to be determined to achieve the optimal solution.
- **Objective Function:** This function represents the goal to be optimized, either maximized (like profit) or minimized (like cost), expressed as a linear combination of decision variables.
- **Constraints:** These are linear inequalities or equalities that define the limitations on the decision variables. They represent the available resources, production capacities, or other restrictions.

Advantages of Linear Programming:

- **Optimal Solutions:** Linear programming guarantees finding the best possible solution for the given objective function and constraints.
- **Efficiency:** It provides a systematic and efficient way to analyze complex problems and arrive at optimal decisions.
- **Versatility:** Applicable to various real-world situations, including production planning, resource allocation, transportation, and financial management.
- **Sensitivity Analysis:** Allows exploring the impact of changes in parameters (like resource availability or cost) on the optimal solution.

Types of Linear Programming Problems:

Linear programming problems can be classified into different types based on the number of decision variables and constraints. Some common types include:

- **Simplex Method:** A widely used algorithm for solving linear programming problems with multiple variables and constraints.

variables, where feasible solutions are represented on a graph. • *Transportation Problem:* Deals with minimizing the cost of transporting goods from sources to destinations. • Assignment Problem: Assigns tasks to individuals in a way that minimizes the overall cost or time.

Solved Examples:

Let's explore a few solved examples to understand how linear programming is applied in real-world scenarios:

Example 1: Maximizing Profit

Problem: A company produces two types of products, A and B. Each unit of product A requires 2 hours of labor and 1 unit of raw material, while each unit of product B requires 1 hour of labor and 2 units of raw material. The company has 40 hours of labor and 20 units of raw material available. The profit per unit of product A is \$5, and the profit per unit of product B is \$4. How many units of each product should the company produce to maximize its profit?

Solution: 1. Define Decision Variables: • Let `x` be the number of units of product A. • Let `y` be the number of units of product B. 2. *Formulate Objective Function:* • Profit = $5x + 4y$ (maximize this) 3. Formulate Constraints: • Labor Constraint: $2x + y \leq 40$ • Raw Material Constraint: $x + 2y \leq 20$ • Non-Negativity Constraints: $x \geq 0, y \geq 0$ 4. **Solve using Graphical Method:** • Plot the constraints on a graph. • Identify the feasible region (area satisfying all constraints). • Find the corner points of the feasible region. • Evaluate the objective function at each corner point. • The corner point with the highest profit value gives the optimal solution. **Optimal Solution:** • Produce 10 units of product A and 10 units of product B to maximize profit at \$90.

Example 2: Minimizing Cost

Problem: A company needs to transport 500 units of a product from two warehouses, A and B, to two retail stores, C and D. The transportation cost per unit from each warehouse to each store is shown in the table below:

	Store C	Store D
Warehouse A	\$2	\$3
Warehouse B	\$4	\$1

The company wants to determine the number of units to transport from each warehouse to each store to minimize the total transportation cost. Solution: 1. Define Decision Variables: • Let `x` be the number of units transported from Warehouse A to Store C. • Let `y` be the number of units transported from Warehouse A to Store D. • Let `z` be the number of units transported from Warehouse B to Store C. • Let `w` be the number of units transported from Warehouse B to Store D. 2. **Formulate Objective Function:** • Total Cost = $2x + 3y + 4z + w$ (minimize this) 3. **Formulate Constraints:** • Supply Constraints: • $x + y = 500$ (Total units from Warehouse A) • $z + w = 500$ (Total units from Warehouse B) • Demand Constraints: • $x + z = 500$ (Total units to Store C) • $y + w = 500$ (Total units to Store D) • Non-Negativity Constraints: $x, y, z, w \geq 0$ 4. Solve using Simplex Method: • Convert the problem into standard form. • Apply the simplex algorithm to find the optimal solution. Optimal Solution: • Transport 500 units from Warehouse A to Store C and 0 units from Warehouse A to Store D. • Transport 0 units from Warehouse B to Store C and 500 units from Warehouse B to Store D.

Warehouse B to Store D. • Minimize the total transportation cost to \$1500.

Applications of Linear Programming:

Linear programming finds applications in a wide range of industries and disciplines: •

Business: • Production Planning: Optimize production schedules and resource allocation to maximize profit. • Inventory Management: Determine optimal inventory levels to minimize costs and avoid stockouts. • Marketing: Allocate advertising budget effectively to reach the target audience. • *Engineering:* • Project Scheduling: Plan and schedule project activities to minimize completion time and cost. • Network Design: Design communication networks to optimize data flow and minimize costs. • Economics: • Resource Allocation: Allocate resources efficiently to maximize economic output. • Portfolio Optimization: Build investment portfolios to maximize returns while minimizing risk. • **Other Applications:** • Transportation: Plan efficient routes for delivery trucks and optimize transportation networks. • Health Care: Schedule hospital staff and allocate medical resources effectively.

Unlocking the Power of Maths: Linear Programming Solved Examples Demystified

Ever found yourself staring at a complex problem with multiple variables and constraints, wishing there was a systematic way to find the absolute best solution? Whether you're a student grappling with textbook assignments, a business owner optimizing resource allocation, or a curious mind exploring the elegance of mathematical optimization, you've likely stumbled upon the fascinating world of linear programming. Linear programming (LP) is a powerful mathematical technique used to determine the best possible outcome in a given situation, typically involving the maximization of profit or minimization of cost. The "linear" part is key: it means we're dealing with relationships that can be represented by straight lines or flat planes, making the problem mathematically tractable and solvable. But let's be honest, the theory can sometimes feel a bit abstract. That's where "maths linear programming solved examples" come into play. Seeing how these principles are applied to real-world (or at least, well-crafted problem) scenarios is often the most effective way to truly grasp the concepts and build confidence. In this comprehensive guide, we'll dive deep into a variety of solved examples, breaking down each step and highlighting the underlying logic. Get ready to become a linear programming pro!

What Exactly is Linear Programming? A Quick Refresher

Before we jump into the juicy examples, a brief recap of the core components of linear programming is in order. Every LP problem generally involves:

- **Decision Variables:** These are the unknown quantities you're trying to determine. Think of them as the levers you can pull to influence the outcome. For example, if you're deciding how many of product A and product B to manufacture, your decision variables would be the quantities of A and B.
- **Objective Function:** This is the mathematical expression that quantifies what you want to achieve - either maximize or minimize. It's always a linear equation. For instance, if each unit of product A yields \$5 profit and each unit of product B yields \$7 profit, your objective function might be $\text{Maximize } Z = 5A + 7B$.
- **Constraints:** These are the limitations or restrictions you face, expressed as linear inequalities or equations. They represent the boundaries within which your decision variables must operate. Examples include limited raw materials, production time, or budget. The goal of linear programming is to find the values of the decision variables that optimize the objective function while satisfying all the given constraints.

The Simplex Method: A Workhorse of Linear Programming

While graphical methods can work for problems with two decision variables, most real-world scenarios involve more. This is where the Simplex Method shines. It's an iterative algebraic

algorithm that systematically moves from one feasible solution (a solution that satisfies all constraints) to another, improving the objective function value at each step until the optimal solution is found. We'll be using this powerful technique in our solved examples.

Example 1: The Classic Manufacturing Problem (Maximization)

Let's start with a common scenario. A furniture company produces two types of tables: dining tables and coffee tables. **Dining tables** require 2 hours of carpentry and 1 hour of finishing. Each dining table yields a profit of \$50. **Coffee tables** require 1 hour of carpentry and 2 hours of finishing. Each coffee table yields a profit of \$40. The company has 100 hours of carpentry available and 80 hours of finishing available per week. How many of each type of table should they produce to maximize their weekly profit?

Step 1: Define Decision Variables

Let x be the number of dining tables produced. Let y be the number of coffee tables produced.

Step 2: Formulate the Objective Function

The company wants to maximize profit. Profit from dining tables = $50x$ Profit from coffee tables = $40y$ Objective function: Maximize $Z = 50x + 40y$

Step 3: Formulate the Constraints

Carpentry Constraint: The total carpentry hours used cannot exceed 100. $2x + 1y \leq 100$
Finishing Constraint: The total finishing hours used cannot exceed 80. $1x + 2y \leq 80$
Non-negativity Constraints: You cannot produce a negative number of tables. $x \geq 0$
 $y \geq 0$

Step 4: Solving using the Simplex Method (Conceptual Overview) For this relatively simple problem, we could visualize it graphically by plotting the constraint lines and identifying the feasible region. The optimal solution would lie at one of the corner points of this region. However, to illustrate the Simplex Method (which is crucial for larger problems), we'll outline the process conceptually.

- Introduce Slack Variables:** To convert inequalities into equations, we introduce slack variables. $2x + y + s_1 = 100$ ($s_1 \geq 0$) $x + 2y + s_2 = 80$ ($s_2 \geq 0$) Our objective function becomes $Z - 50x - 40y = 0$.
- Initial Simplex Tableau:** We set up a tableau representing these equations. The Simplex method then involves a series of iterations, pivoting on specific elements in the tableau, to move towards the optimal solution. This involves identifying the most negative coefficient in the objective row (indicating the variable to enter the basis) and then performing calculations to determine which variable leaves the basis (the "leaving variable").
- Iterative Improvement:** Each iteration effectively "swaps" a non-basic variable for a basic variable in a way that improves the objective function. This continues until all coefficients in the objective row are non-

negative, indicating that the optimal solution has been reached. **Without going into the detailed matrix operations of the Simplex Method for this example (which can be quite extensive for manual calculation and is best handled by software), the solution to this particular problem would be found at one of the corner points of the feasible region. Let's assume, for illustration, that after applying the Simplex method (or by graphical analysis), we find the optimal solution to be producing 40 dining tables and 20 coffee tables.**

Check Constraints:

- Carpentry:** $2(40) + 1(20) = 80 + 20 = 100$ (Satisfied)
- Finishing:** $1(40) + 2(20) = 40 + 40 = 80$ (Satisfied)

Calculate Profit:

$$Z = 50(40) + 40(20) = 2000 + 800 = \$2800$$

This means producing 40 dining tables and 20 coffee tables maximizes the company's profit at \$2800 per week. This example showcases how linear programming helps make informed production decisions based on resource limitations.

Example 2: The Nutrient Blending Problem (Minimization)

Now, let's look at a minimization problem. A farmer wants to create a balanced animal feed by mixing two types of grain, Grain A and Grain B. The feed must contain at least 10 units of nutrient P and at least 15 units of nutrient Q.

- Grain A** contains 2 units of P and 1 unit of Q per kilogram. It costs \$5 per kilogram.
- Grain B** contains 1 unit of P and 3 units of Q per kilogram. It costs \$8 per kilogram.

How many kilograms of each grain should the farmer use to minimize the cost of the feed while meeting the nutrient requirements?

Step 1: Define Decision Variables

Let x be the quantity (in kg) of Grain A used. Let y be the quantity (in kg) of Grain B used.

Step 2: Formulate the Objective Function

The farmer wants to minimize cost. Cost of Grain A = $5x$ Cost of Grain B = $8y$

Objective function: Minimize $Z = 5x + 8y$

Step 3: Formulate the Constraints

- Nutrient P Constraint:** The total units of P must be at least 10. $2x + 1y \geq 10$
- Nutrient Q Constraint:** The total units of Q must be at least 15. $1x + 3y \geq 15$
- Non-negativity Constraints:** $x \geq 0$ $y \geq 0$

Step 4: Solving with the Simplex Method (Minimization)

Minimization problems can be solved using the Simplex Method as well, often by converting them into a maximization problem or by using a dual simplex method. For a direct simplex approach with 'greater than or equal to' constraints, we introduce "surplus variables" (which are subtracted) and "artificial variables" (which are added temporarily) to get the initial basic feasible solution. The process is similar to the maximization case,

involving tableaux and pivoting. The goal is still to reach a state where the objective row is optimal (all non-positive coefficients for maximization or all non-negative coefficients for minimization in the standard form). **Again, for brevity and to focus on the problem setup and interpretation, let's assume the Simplex method (or graphical analysis) reveals the optimal solution to be approximately 3 kg of Grain A and 4 kg of Grain B.** * **Check Constraints:** * Nutrient P: $2(3) + 1(4) = 6 + 4 = 10$ (Satisfied) * Nutrient Q: $1(3) + 3(4) = 3 + 12 = 15$ (Satisfied) * **Calculate Cost:** * $Z = 5(3) + 8(4) = 15 + 32 = \47 Therefore, the farmer should use 3 kg of Grain A and 4 kg of Grain B to achieve the minimum cost of \$47 while meeting the nutrient requirements. This illustrates how linear programming aids in cost-effective resource management.

Example 3: The Diet Problem (More Complex Constraints)

Let's consider a slightly more involved diet problem. An individual needs to consume a minimum of 2000 calories and 100 grams of protein per day. They have two food options: * **Food X:** Provides 400 calories and 20 grams of protein per serving. Costs \$3 per serving. * **Food Y:** Provides 600 calories and 30 grams of protein per serving. Costs \$5 per serving. Additionally, the individual wants to limit their intake of Food Y to no more than 3 servings per day due to digestive issues. What is the optimal number of servings of each food to minimize cost?

Step 1: Define Decision Variables

Let x be the number of servings of Food X. Let y be the number of servings of Food Y.

Step 2: Formulate the Objective Function

Minimize cost. Objective function: Minimize $Z = 3x + 5y$

Step 3: Formulate the Constraints * **Calorie Constraint:** $400x + 600y \geq 2000$ (Simplify by dividing by 200: $2x + 3y \geq 10$) * **Protein Constraint:** $20x + 30y \geq 100$ (Simplify by dividing by 10: $2x + 3y \geq 10$) * Notice that the calorie and protein constraints simplify to the same inequality in this specific case. This can happen and is perfectly valid. * **Food Y Limit Constraint:** $y \leq 3$ * **Non-negativity Constraints:** $x \geq 0$ $y \geq 0$

Step 4: Solving with the Simplex Method (Handling Multiple Constraints) * This problem involves three distinct constraints in addition to non-negativity. The Simplex method will handle these by introducing slack/surplus/artificial variables as needed and iteratively adjusting the tableau. The key is to ensure all constraints are represented and that the algorithm correctly navigates the feasible region defined by these boundaries. * Let's assume, after applying the Simplex method, the optimal solution is found to be $x = 3.5$ servings of Food X and $y = 1$ serving of Food Y. * *

****Check Constraints:**** * **Calories:** $400(3.5) + 600(1) = 1400 + 600 = 2000$ (Satisfied) * **Protein:** $20(3.5) + 30(1) = 70 + 30 = 100$ (Satisfied) * **Food Y Limit:** $1 \leq 3$ (Satisfied) * ****Calculate Cost:**** * **Z** $= 3(3.5) + 5(1) = 10.5 + 5 = \15.5 This solution would indicate that the individual should consume 3.5 servings of Food X and 1 serving of Food Y for a minimum cost of \$15.5. It's worth noting that in real-world diet problems, fractional servings might not be practical, leading to considerations of integer programming, a related but distinct field.

Maths Linear Programming Solved Examples: A Comprehensive Overview Linear programming stands as a foundational pillar in operations research, offering a powerful mathematical approach to optimizing decision-making processes. At its core, linear programming enables individuals and organizations to allocate limited resources efficiently, maximizing profit, minimizing cost, or achieving another defined objective under a set of linear constraints. This method transforms complex real-world problems into structured models, making it accessible and actionable across diverse industries.

What Is Linear Programming? Linear programming is a technique used to find the best outcome—such as maximum profit or minimum cost—in a mathematical model where the relationships are linear and constraints are expressed as equations or inequalities. The core components include decision variables, an objective function to be optimized, and constraints that define the feasible region. This region represents all possible solutions that satisfy the given limitations, such as budget ceilings, material availability, or time restrictions. The optimal solution lies at one of the vertices of this feasible region, a result guaranteed by the fundamental theorem of linear programming.

Key Insights Behind Linear Programming Models One of the most essential insights is the assumption of linearity: both the objective function and constraints must be linear for classical methods to apply. This allows the use of powerful algorithms like the simplex method, which efficiently navigates the feasible region to identify the optimal point. Additionally, understanding how to translate real-world problems into this mathematical framework is crucial. For example, resource allocation, production scheduling, and transportation logistics are naturally suited to linear programming due to their quantifiable inputs and structured constraints. Another critical insight is the concept of duality—every linear program has a dual problem that provides complementary insights. The dual not only

confirms the optimality of the primal solution but also reveals shadow prices, indicating how much the objective value would improve with small changes in resource availability. This dual perspective enriches decision analysis beyond mere optimization.

Practical Applications Across Industries Linear programming finds extensive use in manufacturing, finance, logistics, and energy sectors. In production planning, companies use it to determine the optimal mix of products that maximizes profit while respecting raw material limits and machine capacity. For instance, a factory producing multiple goods can model how many units of each to produce by balancing labor hours, material usage, and market demand—all within a linear framework. In transportation and supply chain management, linear programming optimizes routing and inventory distribution. Shipping companies model delivery networks to minimize transport costs while meeting delivery deadlines and capacity constraints. Similarly, financial institutions apply linear programming in portfolio optimization, allocating investments across assets to maximize returns under risk and budget constraints. Energy providers use linear programming to schedule power generation, balancing fuel costs, emission limits, and demand forecasts. These applications demonstrate how linear programming transforms abstract resource challenges into quantifiable, solvable optimization problems.

Benefits of Applying Linear Programming One of the greatest benefits is its ability to bring clarity and precision to complex decisions. By formalizing constraints and objectives, linear programming removes ambiguity and supports data-driven choices. It enhances efficiency by identifying the most effective

use of scarce resources, reducing waste and operational costs. Moreover, its scalability allows organizations to model large-scale problems with thousands of variables and constraints, making it indispensable for enterprises and government agencies alike. Another advantage lies in its adaptability. While rooted in linearity, linear programming techniques integrate seamlessly with advanced computational tools, including software platforms and solvers like CPLEX and Gurobi. These tools extend its reach, enabling rapid analysis and iterative optimization—critical in dynamic environments where conditions shift frequently.

The Future of Linear Programming in a Data-Driven World As data availability and computational power grow, linear programming continues to evolve. Its synergy with machine learning and artificial intelligence opens new frontiers—predictive models can feed optimized parameters into linear programming frameworks, enhancing both accuracy and responsiveness. In smart manufacturing and real-time logistics, linear programming models are increasingly embedded in automated decision systems, enabling adaptive planning and instant recalibration based on live data. Furthermore, the rise of sustainability goals is driving new applications. Linear programming supports environmental optimization by minimizing carbon footprints, optimizing renewable energy distribution, and balancing ecological constraints with economic performance. This shift positions linear programming not just as a tool for efficiency, but as a strategic asset in building resilient, sustainable systems. Looking ahead, the integration of linear programming with emerging technologies ensures its enduring relevance. As organizations strive to navigate complexity with agility, mastering linear

programming—through both theory and solved examples—remains a vital skill for engineers, analysts, and decision-makers across industries.

What is Linear Programming?

At its core, Linear Programming is a mathematical technique used to optimize a linear objective function, subject to a set of linear constraints. The "linear" aspect is crucial: it means that all relationships within the problem - the objective function and the constraints - can be expressed as straight lines or planes. There are no curves, exponents, or products of variables.

A typical linear programming problem involves:

- 1. Decision Variables:** These are the unknown quantities we need to determine to achieve the optimal solution. For instance, the number of units of product A and product B to produce.
- 2. Objective Function:** This is the linear expression that we aim to maximize (e.g., profit) or minimize (e.g., cost).
- 3. Constraints:** These are the linear inequalities or equalities that represent the limitations or requirements of the problem. Examples include limited raw materials, labor hours, or production capacity.

The goal of linear programming is to find the values of the decision variables that optimize the objective function while satisfying all the given constraints. This is also known as finding the [feasible region](#) that yields the best outcome.

Formulating Linear Programming Problems

Before any solving can occur, the first and arguably most critical step is to accurately formulate the problem into a mathematical model. This involves identifying the decision variables, the objective function, and the constraints. Let's illustrate this with a classic example.

Example 1: The Furniture Manufacturing Problem

A furniture company manufactures two types of tables: dining tables and coffee tables. The manufacturing process for each table requires a certain amount of carpentry time and finishing time. The company has a limited number of hours available for carpentry and finishing each week. The profit generated from each dining table is \\$50, and from each coffee table is \\$30. The company wants to determine how many of each type of table to produce to maximize its total profit.

Information Provided:

1. **Carpentry Time:** 3 hours per dining table, 2 hours per coffee table. Total available: 120 hours per week.
2. **Finishing Time:** 2 hours per dining table, 1 hour per coffee table. Total available: 70 hours per week.
3. **Profit:** \\$50 per dining table, \\$30 per coffee table.

Formulation Steps:

1. Identify Decision Variables:

1. Let x = the number of dining tables to produce.
2. Let y = the number of coffee tables to produce.

2. Define the Objective Function: The company wants to maximize profit.

1. Maximize $Z = 50x + 30y$ (where Z is the total profit).

3. Define the Constraints:

1. **Carpentry Constraint:** The total carpentry time used cannot exceed 120 hours.

$$3x + 2y \leq 120$$

2. **Finishing Constraint:** The total finishing time used cannot exceed 70 hours.

$$2x + y \leq 70$$

3. **Non-negativity Constraints:** The number of tables produced cannot be negative.

$$x \geq 0$$

$$y \geq 0$$

The complete LP formulation is:

Maximize $Z = 50x + 30y$

Subject to:

$$3x + 2y \leq 120$$

$$2x + y \leq 70$$

$$x \geq 0, y \geq 0$$

Solving Linear Programming Problems Graphically

The graphical method is a visual approach to solving linear programming problems, particularly effective for problems with two decision variables. It involves plotting the constraints on a graph to define the **feasible region**, and then evaluating the objective function at the corner points of this region.

Example 1 Solved Graphically (Continued)

Using the formulation from Example 1:

1. Graph the Constraints:

For each inequality, we'll first treat it as an equation to find the boundary line. Then, we'll determine the region that satisfies the inequality.

1. Constraint 1: $3x + 2y \leq 120$

If $x=0$, $2y = 120 \implies y = 60$. Point: (0, 60)

If $y=0$, $3x = 120 \implies x = 40$. Point: (40, 0)

Draw a line connecting (0, 60) and (40, 0). For $\leq$, shade the region below the line (towards the origin).

2. Constraint 2: $2x + y \leq 70$

If $x=0$, $y = 70$. Point: (0, 70)

If $y=0$, $2x = 70 \implies x = 35$. Point: (35, 0)

Draw a line connecting (0, 70) and (35, 0). For $\leq$, shade the region below the line (towards the origin).

3. Non-negativity Constraints: $x \geq 0$ and $y \geq 0$. This restricts us to the first quadrant of the graph.

2. Identify the Feasible Region: The feasible region is the area on the graph where all shaded regions (satisfying all constraints) overlap. It will be a polygon.

3. Determine the Corner Points: The corner points (vertices) of the feasible region are the potential locations for the optimal solution. These are found at the intersections of the constraint

lines.

1. Point A: Intersection of $x=0$ and $y=0$ (origin). Point: (0, 0)

2. Point B: Intersection of $y=0$ and $2x + y = 70$.

Substitute $y=0$ into $2x+y=70$: $2x = 70 \implies x = 35$.

Point: (35, 0)

3. Point C: Intersection of $3x + 2y = 120$ and $2x + y = 70$.

From $2x + y = 70$, we get $y = 70 - 2x$. Substitute this into the first equation:

$$3x + 2(70 - 2x) = 120$$

$$3x + 140 - 4x = 120$$

$$-x = 120 - 140$$

$$-x = -20 \implies x = 20$$

Now find y : $y = 70 - 2(20) = 70 - 40 = 30$. Point: (20, 30)

4. Point D: Intersection of $x=0$ and $3x + 2y = 120$.

Substitute $x=0$ into $3x+2y=120$: $2y = 120 \implies y = 60$. Point: (0, 60)

4. Evaluate the Objective Function at Each Corner Point:

Substitute the coordinates of each corner point into the objective function $Z = 50x + 30y$.

1. At (0, 0): $Z = 50(0) + 30(0) = 0$

2. At (35, 0): $Z = 50(35) + 30(0) = 1750$

3. At (20, 30): $Z = 50(20) + 30(30) = 1000 + 900 = 1900$

4. At (0, 60): $Z = 50(0) + 30(60) = 1800$

5. Determine the Optimal Solution: The corner point that yields the highest value for the objective function is the optimal solution.

In this case, the maximum profit is \$1900, occurring when $x = 20$ and $y = 30$. Therefore, the company should produce 20 dining tables and 30 coffee tables to maximize its profit.

Solving Linear Programming Problems Using the Simplex Method

While the graphical method is excellent for two variables, it becomes impractical for problems with three or more decision variables. The [Simplex Method](#), developed by George Dantzig, is an algebraic algorithm that can solve linear programming problems with any number of variables. It systematically moves from one feasible solution to an adjacent one, improving the objective function at each step until the optimal solution is found.

The Simplex Method typically involves the following steps:

1. Converting inequalities to equalities by introducing slack or surplus variables.
2. Setting up the initial Simplex tableau.
3. Identifying the pivot column (most negative coefficient in the objective row for maximization).
4. Identifying the pivot row (minimum ratio of the right-hand side to the pivot column element).
5. Performing row operations to make the pivot element 1 and other elements in the pivot column 0.
6. Repeating the process until all coefficients in the objective row are non-negative (for maximization).

Example 2: A Production Planning Problem (Simplex Method)

A company produces three products: A, B, and C. The production of each product requires time on three different machines: Machine 1, Machine 2, and Machine 3. The profit per unit and the machine hours required per unit are given below. The total hours available for each machine are also provided. The company wants to maximize its total profit.

Information Provided:

Product	Profit per Unit	Machine 1 (hrs/unit)	Machine 2 (hrs/unit)	Machine 3 (hrs/unit)
A	\\$10	1	2	1
B	\\$15	2	1	3
C	\\$20	3	3	2

Available Machine Hours:

1. Machine 1: 50 hours
2. Machine 2: 70 hours
3. Machine 3: 60 hours

Formulation:

1. Let x_1 = units of Product A
2. Let x_2 = units of Product B
3. Let x_3 = units of Product C

$$\text{Maximize } Z = 10x_1 + 15x_2 + 20x_3$$

Subject to:

$$x_1 + 2x_2 + 3x_3 \leq 50 \text{ (Machine 1)}$$

$$2x_1 + x_2 + 3x_3 \leq 70 \text{ (Machine 2)}$$

$$x_1 + 3x_2 + 2x_3 \leq 60 \text{ (Machine 3)}$$

$$x_1, x_2, x_3 \geq 0$$

Simplex Method Steps:

1. Convert to Standard Form: Introduce slack variables (s_1, s_2, s_3) to convert inequalities into equalities.

$$\text{Maximize } Z = 10x_1 + 15x_2 + 20x_3 + 0s_1 + 0s_2 + 0s_3$$

Subject to:

$$x_1 + 2x_2 + 3x_3 + s_1 = 50$$

$$2x_1 + x_2 + 3x_3 + s_2 = 70$$

$$x_1 + 3x_2 + 2x_3 + s_3 = 60$$

$$x_1, x_2, x_3, s_1, s_2, s_3 \geq 0$$

2. Initial Simplex Tableau: Create the initial tableau. The objective row is derived from the objective function by moving all variables to the left side ($Z - 10x_1 - 15x_2 - 20x_3 = 0$).

Basis	x_1	x_2	x_3	s_1	s_2	s_3	RHS
1	1	0	0	0	0	0	10
2	0	1	0	0	0	0	15
3	0	0	1	0	0	0	20
4	0	0	0	1	0	0	50
5	0	0	0	0	1	0	70
6	0	0	0	0	0	1	60

3. Iteration 1:

- 1. Pivot Column:** The most negative value in the Z-row is -20 (under x_3). So, x_3 is the entering variable.

2. Pivot Row: Calculate ratios:

\$s 1\$: 50 / 3 = 16.67

\$s 2\$: 70 / 3 = 23.33

\$s 3\$: $60 / 2 = 30$ The minimum ratio is 16.67,

corresponding to the s_1 row. So, s_1 is the leaving variable. The pivot element is 3.

3. Row Operations:

1. Make the pivot element 1: $R_1' = R_1 / 3$
2. Make other elements in the pivot column 0: $R_2' = R_2 + 10 R_1'$, $R_3' = R_3 - 2 R_1'$, $R_4' = R_4 - 1 R_1'$

After Iteration 1:

Basis	x_1	x_2	x_3	s_1	s_2	s_3	RHS
	Z	-10/3	-5/3	0	20/3	0	1000/3
	x_3	1/3	2/3	1	1/3	0	50/3
	s_2	2 - 2/3 = 4/3	1 - 4/3 = -1/3	0	-2/3	1	70 - 100/3 = 110/3
	s_3	1 - 1/3 = 2/3	3 - 2/3 = 7/3	0	-2/3	0	60 - 50/3 = 130/3

4. Iteration 2:

- 1. Pivot Column:** The most negative value in the Z-row is $-10/3$ (under x_1). So, x_1 is the entering variable.

2. Pivot Row: Calculate ratios:

\$x\$ 3\$: $(50/3) / (1/3) = 50$

\$s 2\$: $(110/3) / (4/3) = 110/4 = 27.5$

s_3 : $(130/3) / (2/3) = 130/2 = 65$ The minimum ratio is 27.5, corresponding to the s_2 row. So, s_2 is the leaving variable. The pivot element is $4/3$.

3. Row Operations:

1. Make the pivot element 1: $R_2'' = R_2' / (4/3)$
2. Make other elements in the pivot column 0: $R_Z'' = R_Z' + (10/3) R_2''$, $R_1'' = R_1' - (1/3) R_2''$, $R_3'' = R_3' - (2/3) R_2''$

After Iteration 2:

Basis	x_1	x_2	x_3	s_1	s_2	s_3	RHS
Z	0	-15/4	0	0	10/4	0	$1000/3 + (10/3)*(110/4) = 1000/3 + 1100/12 = 1350/3 = 450$
x_3	0	7/4	1	1/2	-1/4	0	$50/3 - (1/3)*(110/4) = 50/3 - 110/12 = 90/12 = 7.5$
x_1	1	-1/4	0	-1/2	3/4	0	$110/4 = 27.5$
s_3	0	-1/2	-1/2	1	$130/3 - (2/3)*(110/4) = 130/3 - 220/12 = 340/12 = 85/3$		

5. Check for Optimality: All coefficients in the Z-row are now non-negative (0 or positive). Therefore, we have reached the optimal solution.

Optimal Solution:

The basic variables are x_3 and x_1 .

1. $x_1 = 27.5$
2. $x_2 = 0$
3. $x_3 = 7.5$

The maximum profit is $Z = 450$.

This means the company should produce 27.5 units of Product A and 7.5 units of Product C to achieve a maximum profit of \$450. Note that producing fractional units might need interpretation in a real-world context (e.g., batches or average production).

Sensitivity Analysis and Interpretation

Once an optimal solution is found, it's crucial to understand its

implications. [Sensitivity analysis](#) explores how changes in the problem's parameters (like profit margins or resource availability) affect the optimal solution. This adds a layer of practical insight to the mathematical results.

Key interpretations from solved examples include:

- 1. Resource Utilization:** Are all resources fully utilized (binding constraints) or is there slack (non-binding constraints)?
- 2. Shadow Prices (Dual Values):** These indicate the marginal increase in the objective function for a one-unit increase in a constraint's right-hand side. For example, a shadow price for Machine 1 would tell us how much profit increases if we have one extra hour of Machine 1 available.
- 3. Range of Optimality:** For how much can the coefficients in the objective function change before the optimal solution changes?

Applications of Linear Programming

The versatility of [linear programming applications](#) is vast and impacts numerous industries:

- 1. Operations Research:** Resource allocation, scheduling, inventory management.
- 2. Finance:** Portfolio optimization, capital budgeting.
- 3. Marketing:** Advertising budget allocation, sales territory design.
- 4. Production Management:** Production planning, mix optimization, facility location.
- 5. Transportation:** Routing, logistics, network flow optimization.
- 6. Agriculture:** Crop planning, feed mix optimization.

Questions & Answers About maths linear programming solved examples

No	Question	Answer
1	What's the first step when approaching a linear programming problem with a solved example?	The crucial first step is to clearly define the decision variables. These represent the quantities you need to determine, like the number of products to manufacture or the amount of resources to allocate.
2	How do solved linear programming examples help visualize the feasible region?	Solved examples often show how to graph the constraint inequalities. The intersection of these shaded regions forms the feasible region, which graphically represents all possible combinations of decision variables that satisfy the constraints.
3	In solved examples, why is identifying the objective function so important?	The objective function represents what you want to maximize or minimize (e.g., profit, cost). Solved examples demonstrate how to formulate this function using the decision variables, as it's the target to optimize within the feasible region.
4	When looking at a solved linear programming problem, what does the 'corner point theorem' mean?	The corner point theorem states that the optimal solution (maximum or minimum of the objective function) will always occur at one of the vertices (corner points) of the feasible region. Solved examples illustrate evaluating the objective function at each corner.
5	How do solved examples handle linear programming problems with more than two variables?	For problems with more than two variables, direct graphical representation is impossible. Solved examples often introduce the Simplex method, an algorithmic approach that iteratively moves through corner points until the optimal solution is found.
6	What's a common pitfall in solved linear programming examples, and how can I avoid it?	A common pitfall is misinterpreting the constraints. Always double-check that your inequalities correctly represent the limitations given in the problem. Carefully read and rephrase each constraint before setting it up.
7	Can you explain the concept of 'slack' and 'surplus' variables in solved linear programming examples?	Slack variables are added to 'less than or equal to' constraints to convert them into equalities, representing unused capacity. Surplus variables are subtracted from 'greater than or equal to' constraints, representing excess. Solved examples use these to facilitate algebraic methods like the Simplex method.
8	What's the practical takeaway from a solved linear programming example for business decision-making?	Solved examples demonstrate how linear programming can provide optimal strategies for resource allocation, production planning, and cost minimization, leading to increased efficiency and profitability by making data-driven decisions.
